

Coding challenge overview

This is a problem that we have designed to be as similar as possible to some part of the actual daily work. We encourage you to use any tool or vibe-coding app that you are comfortable with in order to approach it. As a matter of fact, we have already implemented it completely by vibe-coding. This task is simply too large to be done by fully manual coding. You have 24 hours to complete it, with vibe-coding it should be doable in significantly less time.

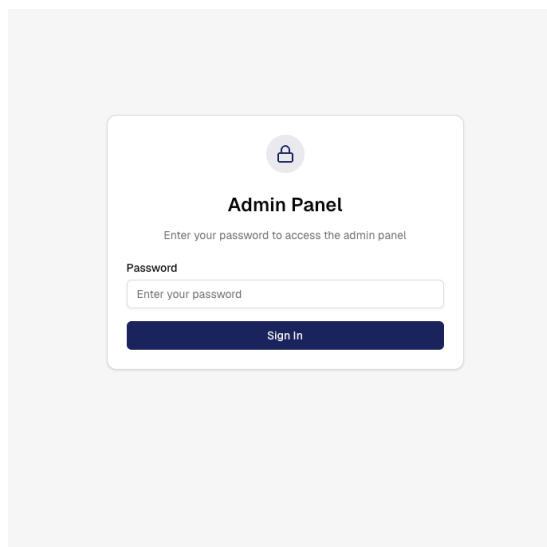

We do not expect a perfect implementation from you, but we do expect that you can reason about the requirements, understand the architecture (even if AI writes the code) and are able to articulate it well, and explain your design decisions. **This is as much about evaluating communication skills as it is about evaluating technical ones.**

Task

We manage a lot of data about companies and their attributes such as names, urls, headquarter countries, and sector assignment. We would like to create an Admin Panel to be used internally where non-technical colleagues can easily browse and edit parts of our database.

Each company has a few attributes (name, url, HQ country, sector(s)).
Each sector has a name and a radius attribute, and sectors can have other sectors as parents.

Below are some screenshots:

Select Companies

Choose companies to report on by uploading a CSV file or selecting sectors

Upload CSV

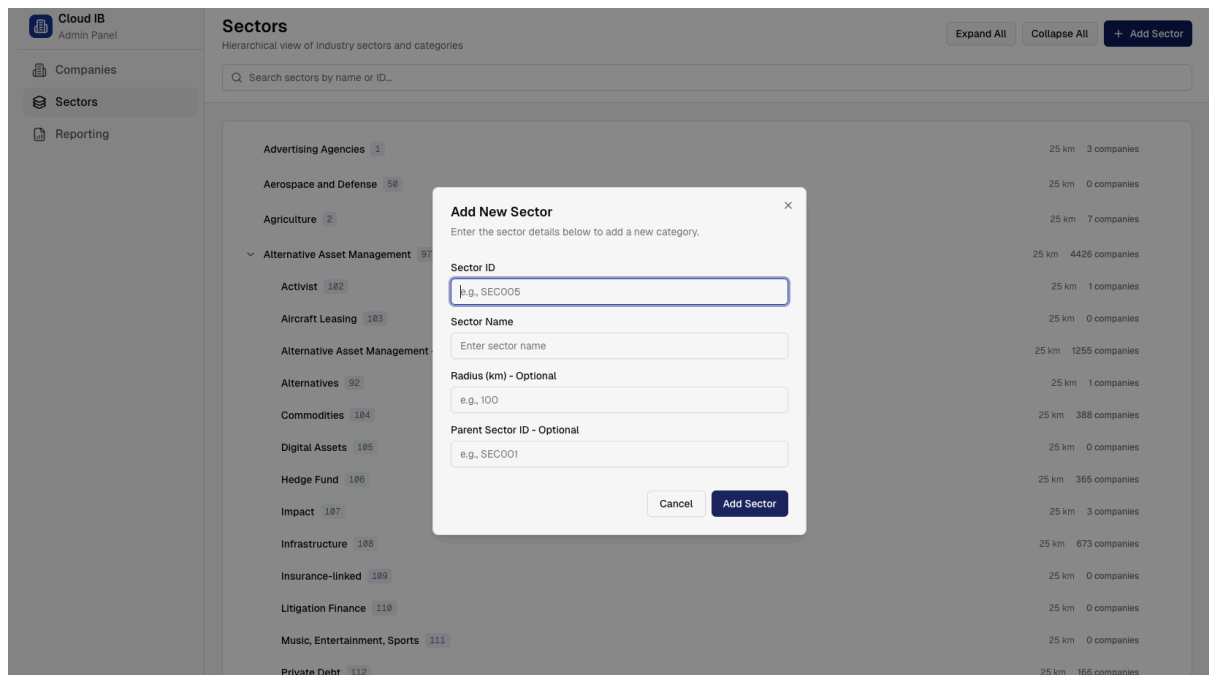

Select Sectors

Drop your CSV file here, or click to browse

File must contain either 'cib_id' or 'url' column

Select File

(on the above screen the user can upload a CSV file and get a table if/what sector each company is assigned to)

We ask you to implement a similar Admin Panel which allows for viewing / searching / linking companies and sectors. Do use the screenshots for inspiration or even follow them exactly for your UI. In a separate attachment we will send you 3 CSV files with all sectors and a sample of 1000 companies (and the linking). Feel free to augment the dataset with more synthetically-generated companies if you like.

You should create a backend in Python (using Flask / FastAPI), a front-end in React, a database (using Postgres or SQLite), and have these all containerized and ready for deployment (i.e. corresponding docker-compose, Dockerfile). If you can deploy this somewhere online and send as a link even better, but this is not a requirement. You should send us all components in a zip file (or link to a GitHub repo) and be prepared to demo the running system in a video call.

It would be particularly nice if you can explain to us where AI does well, where it falls short, what were the challenges you encountered and how to make such a project easily maintainable beyond a one-off exercise (i.e. would <https://agents.md/> help in practice?)

Good luck!
